FANOX

PROTECTION AND CONTROL

FANOX introduces its complete range of protection, control and measuring electronic devices for application in the Industry.

We are leaders in the electronic protection of industrial electric motors. Everyday our relays prevent the burnout of any number of motors, saving on repair costs and process downtimes.

Among the many technical advantages of these relays, we highlight the following:

- **Thermal memory,** which continuously creates a model of the heating and cooling of the motor during its start-up, running, overload and shutoff cycles.

- **Immediate detection** of phase failure, including at low motor loads, with a rapid shutdown of the motor which prevents costly breakdowns.

- **Display module,** of the size of a pushbutton of 22mm in diameter, which, mounted on the outside of the panel or of the motor control center, allows rapid detection of the cause of the motor shutdown.

This protection has become the most reliable and cost effective on the market, and far surpasses the functions offered by other conventional protection devices, such as thermal relays, thermal-electronic relays, manual motor starters or thermal magnetic circuit breakers.

Our relays are ideal for protecting pumps, compressors, fans and all types of industrial motors having to withstand multiple start-up/shutoff cycles, heavy start-ups or that work in high-temperature locations.

Models G and BG are approved by PTB (Physikalisch-Technische Bundesanstalt) of Germany for the protection of EEx e motors that run in explosive or hazardous areas.

Other products of interest include earth leakage relays, especially those which incorporate the toroidal transformer and relay in one single unit.

The range of generator control and protection devices, voltage monitors, phase and frequency relays, timers, manual motor starters and electrical multimeters complete a wide selection of products for application in the Industry.

A complete package of technical information, installation instructions, settings, applications and a selection guide comes included, and provides all the guidelines and instructions necessary for proper use.

- $I<$ **Undercurrent**
- cos φ **Underload**
- **Phase imbalance or phase loss**
- **Overtemperature**
- **Phase sequence**

Basic motor protection

For motors of low and medium power in several applications as compressors, ventilators, surface mounted pumps, conveyor belts, machine tools, and in general to protect motors which need dependable and accurate protection relays for every type of start.

Its 3 trip classes cover any type of starting or working cycle.

Integral motor protection

For whatever power motors (1 to 630 A and over), in several applications as surface mounted pumps, compressors, mixers, ventilators, elevators, cranes, industrial refrigeration and in general for those motors requiring a complete protection where the overtemperature (by means of PTC sensor) and a wrong phase sequence protections are required.

Its 7 trip classes cover all type of starting or working cycle.

- *For 3-phase motors up to 1000 Vac. Passing through wires*
- *Broad range of current adjustment (1 to 630 A and over)*
- *Precise motor heating and cooling memory, reproduces its thermal image*
- *Visual indication of tripping cause*

Pumps protection

Suitable where the undercurrent (running without load) is critical, as submersible pumps, surface pumps, etc. In these cases, when the equipments run without load (dry well) the relay trips by undercurrent.

Pumps protection

Underload protection by cos φ

For application in pumps and other systems where running without load is critical (dry well, transmission belt broken, etc). With the underload protection by cos φ it is ideal when the motor is over-sized, such as submersible pumps in gasoline stations where, at every pumping start-up operation, the motor can work even at the 20% of its nominal load.

External display module

By means of this plug-in optional accessory, the relay status can be seen and reset from the exterior of the electrical panel board.

Easy to install. Size of a Ø22 mm push button.

Suitable for motor control centres (MCC) and panel boards.

This optional display module is mounted externally, e.g. on the panel door or a draw-out unit in a motor control centre (MCC) and connected to the relay by a flat cable (length 2 meters).

The module has the appropriate LED's to signal the trip cause and a reset push-button.

Weight: 0,05 kg.

Protection degree: IP50

Relays for the protection of EEx e motors

- *Approved by PTB for EEx e motors*
- *For 3-phase motors up to 1000 Vac*
- *Currents from1,5 to 630 A and higher*
- *With thermal memory*
- *Visual indication of tripping cause*

Protections

I> **Overload**

Phase imbalance or phase loss

Overtemperature

Protection of motors in explosive or hazardous areas

For EEx e motors of any power rating, and currents up to 630A and higher, which work in explosive or hazardous areas such as the petrochemical industry, plastic factories, mines, etc. The relay is installed away from the explosive area.

The overload LED starts to blink from 1,1 x I_B.

In the event of a phase loss the relay trips in less than 3s, even when the motor is at low load.

Relay to be used with the external display module

With the same features and applications as the G17 relay, the BG17 relay incorporates an external display module which shows the status of the relay and allows it to be reset from outside of the panel or the motor control center (MCC).

As the BG17 is designed for use with the ODG display module, it does not include the LED signals on the front of the relay itself.

ODG display module

This module, which is the size of a pushbutton of Ø22 mm, is mounted outside on the panel door or on the front of the motor control center (MCC), and is connected to the relay by means of a 2 meters long flat cable.

To see the state of the relay or reset in the event of a tripping, it is not necessary to open the door or remove the MCC, since the module includes the corresponding identifying LED's and the reset button.

Weight: 0,05 Kg.

PTB approval:

G and BG relays have been approved by the **Physikalisch-Technische Bundesanstalt-PTB** for the protection of EEx e protected explosion motors (DIN EN 50019 / DIN VDE 0170 /DIN VDE 0171 part 6) according to the stipulations and requirements of PTB.

PTB report no. PTB Ex 3.43-30004/00

For dimensions, installation, adjustments and curves see pages 18 and following.

Frequency monitoring relay

- Suitable for monitoring the frequency of a single phase or 3-phase system.
- Suitable for generators, alternators and electrical generator sets.
- Maximum and minimum thresholds can be adjusted separately.
- Two independent output relays.

Lifts temperature control relay

- It controls the temperature of the lift motor room (relay + external module ODT2) or the temperature inside of the switchboard for those lifts without motor room (relay + internal sensor INT2).
- Designed according to the EN 81-1 standard and complying with the European Union Directive for Lifts (95/16/CE).
- Two adjustable temperature thresholds.
- 22,5 mm wide.

Thermistor protection relay

- Controls the temperature with the use of thermistors (PTC sensors)
- Detects short-circuits and breakage in the circuit of sensors.
- Protects the motors against overtemperature caused by excess surrounding temperature, insufficient ventilation or cooling, etc.
- Applicable in transformers and other machines.
- 22,5 mm wide.

Three-phase voltage relay

- Protects three-phase installations against voltage variations between phases, incorrect sequence of phases and phase loss.
- Minimum and maximum thresholds adjustables (two potentiometers).
- Tripping time delay adjustable (two potentiometers).
- Model U3S-420 is valid for 400 and 440 nominal V.
- 22,5 mm wide.

Three-phase voltage relay

- Suitable to protect three-phase installations against variations in main voltage. Sensitive to incorrect phase sequence.
- Applicable in generators, automatic transfer setups, etc.
- Maximum and minimum thresholds can be adjusted separately.
- Two independent output relays.

Three-phase voltage relay

- Suitable to protect three-phase with neutral installations against variations in main voltage and loss of neutral. Sensitive to incorrect phase sequence.
- Applicable in generators, automatic transfer setups, etc.
- Maximum and minimum thresholds can be adjusted separately.
- Two independent output relays.

Working principles: The toroidal transformer is installed between the source and the load. The system works on the current balance principle. In a correct installation the vector sum of the currents is zero and the relay will not trip.

In case of an insulation fault on the circuit a leakage current flows to earth. Now the vector sum of the current passing through the transformer is not zero, this imbalance is detected by the transformer that induces a current in the secondary winding which is connected to the relay.

If the fault level is higher than the selected sensitivity and when the trip time delay has elapsed, the relay trips and actuates on the shunt trip of a circuit breaker or on the coil of a contactor interrupting therefore the supply to the load.

The dimensioning of the toroidal transformer depends on the diameter of all active wires (not earth conductors) put through the transformers.

Electrical multimeters

- ***Measure and display up to 30 parameters of a three phase line with or without neutral. True RMS values.***
- ***All the values can be read without making program changes.***
- ***Reduced size 96x96 mm. Flush mounting in panel***

Timers

- ***Multifunction digital timer***
- ***Possibility of programming up to 9 different times. Each time can be set from 0,1 seconds to 99 hours***
- ***With built-in battery which allows timer to be programmed without connecting to auxiliary voltage. Complete battery discharge does not affect operation or adjustment settings.***

- For control and automation systems in industry.
- Command contact with 5 programmable functions.
- 2 digit, 7 segment LED displays and push-buttons provide programming, and during operation allow for monitoring of the time period and review the programmed settings.
- 45 mm module size, 35 mm wide. DIN EN 50022-35 rail mounting.

Programmable parameters

- Initial state of outpout relays: energized (1H) or de-energized (1L).
- Working mode: cycle (C1) or non-cycle (C0).
- Number of different times per program: up to 8 in cycle mode and up to 9 in non-cycle.
- Time setting range: from 0,1 seconds to 99 hours.
- Command contact.

Timing with partial shutdown by command contact
1L - CO - cl

Command contact Can be switched on in two ways:

- By closing an external voltage free contact between M and S
- By connecting 5-35 Vac,dc between M(+) and R(-)

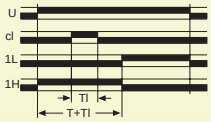
One of the following arrangements can be programmed:

Each diagram represents the effect of the command contact for the two initial states of the output relay: de-energized (1L) and energized (1H).

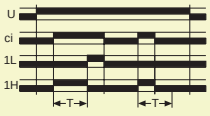
cu **Switched off contact**
Its function is blocked

cr **Reset contact**
When connected the output relay is de-energized; upon disconnecting, the programmed timing starts.

cl **Lock contact**
A partial shutdown of the timing takes place during its operation.



ci **Delay on contact**
When disconnected the output relay is de-energized; when connected the programmed timing starts.



co **Delay off contact**
When disconnected the output relay is de-energized. When connected, the relay is energized. When disconnected again, the programmed timing starts.

Accessories

Current transformers

- Up to 1000 A of primary current.
- Transformers ratio .../5.
- Sealable connection terminal box, metal brackets for fitting and bus-bar holders included.

Thermistor sensors

- Connected to GL, G, BG or ST relays protect motors against overtemperature.
- PTC. Positive temperature coeficient
- PTC 120, for internal mounting. Temperature threshold 120°C.
- PTCEX 70, for external mounting. Temperature threshold 70°C.

Motor and generator protection relays. Installation and setup

The motor protection

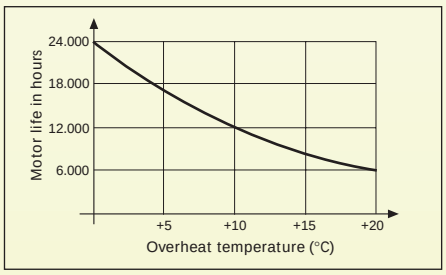
The electric motor is one of the most important operating devices in industry. Many times the shutdown of an industrial process is caused by a simple motor. High-cost production runs and valuable machinery can become paralysed at great cost, even more than the cost of rewinding the motor.

Experience shows us that motor protection continues to be a problem, based on the number of breakdowns occuring every day.

Over 60% of failures are due to causes produced by overheating of the motor winding. These can be detected, and prevented, by measuring and analysing the current being absorbed by the motor, or by controlling temperature limits of the winding. The major causes are as follows:

- Overloads
- Locked rotor
- Over and undervoltage
- Phase imbalance or phase loss
- Long and heavy start-ups
- Excessive operating cycling
- Heating from non-electric causes
- Inadequate motor ventilation
- High room temperature
- Insulation failure

The following diagram shows the dramatic decrease suffered in the electric life of a motor due to the excessive heat of the motor windings (Montsinger's rule).



As one can see, a 10ºC increase in temperature reduces the useful life of the motor by half.

The most reliable protection option, which is becoming more commonly used, is the one consisting on:

- Fuses or circuit breakers for short-circuit protection.
- Electronic motor protection relays with thermal memory.
- Contactors for motor control.

FANOX relays

Our R+D Division has allowed FANOX to develop a wide range of easy-to-install and operate electronic relays, at truly competitive prices, which will save downtime and money.

FANOX motor protection relays work with the current measured at every moment. These currents, which are read by three current transformers built into the relays, are electronically processed and used to modelize the thermal image of the motor, and to compare them with the values set in the relay.

The three power supply connections to the motor are not directly connected to the relay, but pass through its corresponding holes.

This provides motor protection against:

- Overloads: since the relay creates a model of the thermal image of the motor during its heating and cooling cycles. In this way, in overload conditions, the relay will take into consideration previous operating conditions of the motor, and will trip faster if the relay has detected other previous overloads. This thermal memory is independent of the auxiliary voltage supply of the relay so that it remains active even when this voltage is cut off or disconnected. The different tripping curves available for selection in the relays allow for precise adjustment to any kind of motor start-up or work cycle.
- Underloads: protects motors against no-load working, which is very important for pumps (dry running).
- Phase imbalance and phase loss: even if the motor is running below its full load current.
- The incorrect phase sequence detection is highly important when the correct phase sequence is critical as in compressors, pumps, fans and other applications.

For protection against no-load operation when the motor is oversized, underload protection by cos φ has been incorporated so that the relay differentiates precisely between very low load and no-load operations, and drops out in the latter case.

In addition, when the relay is connected to thermistor sensors (PTC), it protects the motor against electrical and non-electrical overheating.

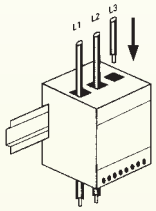
A visual display of the tripping reason allows maintenance personnel to identify and immediately act on the underlying causes. The use of the OD display makes this operation much easier.

All of this make FANOX relays the ideal protection for your motors (pumps, compressors, fans, etc).

1. Installation

1.1. General

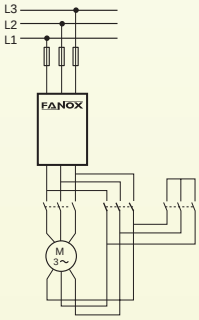
For correct installation and operation of the relays, please bear on mind the following considerations:



- After being fixed to the DIN rail, the cables for the three phases should be passed through the holes in the relay.

  The maximum section of 700V insulated wires that can pass through the holes are:

C	16 mm²
GL, P, PF, G, BG, GEN	35 mm²



- In star-delta starting, the relay or the current transformers must be installed between the fuses or circuit breaker and the contactor.

- Relays used in combination with frequency inverters:

a) GL relays with the selector for phase sequence in "ON" and P and PF relays: don't use in combination with inverters.

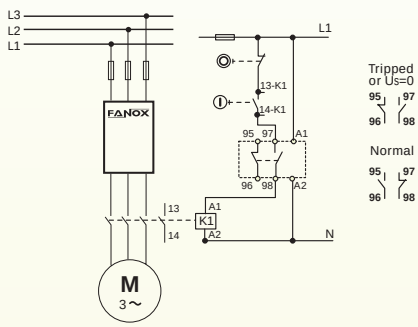
b) GL relays with the selector for phase sequence in "OFF" and C, G and BG: the relay or current transformers and the relay's auxiliary supply shouldn't be connected at the inverter output.

- Connection between the PTC sensors and the relay (GL, G and BG). For PTC connection lengths over 100 m or when the influence of high frequency transient voltages is expected, it is adviseable to use screened cable and connect the screen to terminal T1.

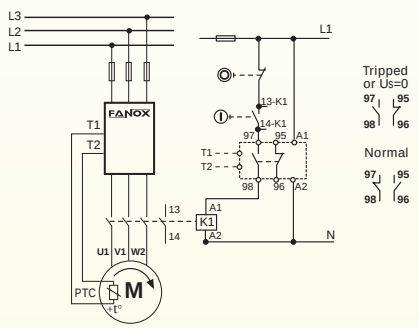
Note: every relay comes with its instruction manual providing information on its correct installation and setup.

1.2. Wiring diagrams

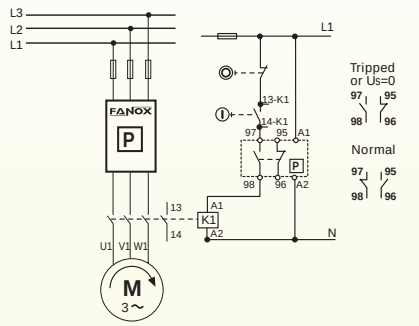
C



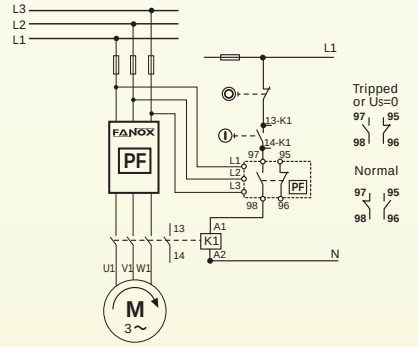
GL-G-BG



P

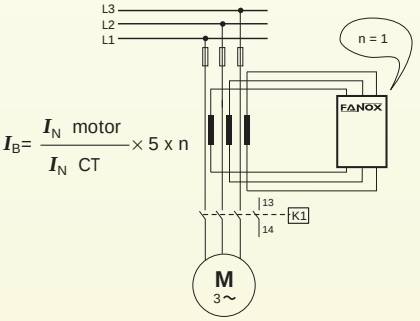


PF



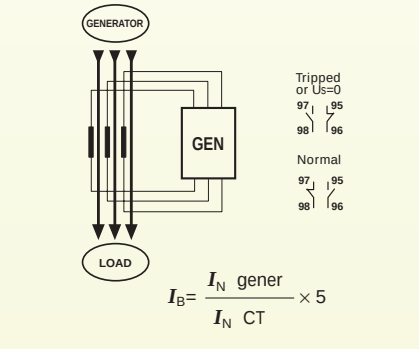
C-GL-P-PF-G-BG

With current transformers



$$I_B = \frac{I_N \text{ motor}}{I_N \text{ CT}} \times 5 \times n$$

GEN 10



$$I_B = \frac{I_N \text{ gener}}{I_N \text{ CT}} \times 5$$

2. Setup procedure. C, GL, P, PF, G, BG and GEN

Basically the main steps to follow are described below:

- Adjust the I_B current of the relay (C, GL, P, PF, G, BG and GEN). See 2.1.
- Select and adjust the trip class (C, GL, P and PF) or the tripping time (G, BG and GEN). See 2.2. and 2.3.
- Select and adjust the underload tripping level by cos φ and the trip delay (PF). See 2.4.
- Select and adjust the undercurrent tripping level (P). See 2.5.
- Select (ON-OFF) the protection against incorrect phase sequence (GL). See 2.6.
- Select the reset mode to manual or automatic (P and PF). See 2.7.

After installation and setup and before starting up the motor, make sure the motor is in a cold state. This will ensure that both, the relay and motor start to operate with the same thermal memory (cold condition).

2.1. Current setting I_B. C, GL, P, PF, G, BG and GEN

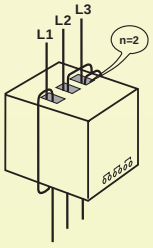
Adjust the current I_B on the corresponding dipswitches (full load current). When setting the current take into account that the base current of the relay always remain added to the current selected with the dipswitches in "ON" position (to the right). The total addition is the set current I_B.

Overload tripping current from 1,1 x I_B.

a) For motor or generator rated currents (I_N) within the range of the relay, the setting I_B must be equal to the I_N of the motor or generator.

$$I_B = I_N$$

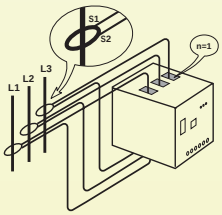
b) For motor rated currents below the range of the relay, the setting I_B must be equal to the rated current of the motor I_N multiplied by the number of times that the conductors have been passed through the relay holes.



$$I_B = I_N \times n$$

c) For motor or generator rated currents (I_N) above the range of the relay, use three current transformers .../5 in combination with the corresponding relay.

$$I_B = \frac{I_N \text{ mot/gen}}{I_N \text{ CT}} \times 5 \times n$$



2.2. Tripping times GEN

Select the tripping curve suitable for the good performance of the generator on the 4 positions dipswitch (trip time setting).

The selected curve will correspond to the result of the addition of the dipswitches in "ON" position (to the right).

2.3. Trip class / tripping time (IEC 947-4-1). C, GL, P and PF / G and BG

The different trip classes enable the user to select the overload protection according to the various motor applications in either short or long start-ups.

The class number or the tripping time refers to the maximum approximate time in seconds allowed for the direct start of the motor from a cold condition.

To select the trip class or tripping time (t_{6xI_B}) use the corresponding dipswitches. The recommended values are listed in the following tables.

Motor with direct start-up

Start time (s) RPM t_s	Trip classes											Trip time t_{6xI_B}	
	Models											Models	
	C9	C21	C45	GL16	GL40	GL90	P19	P44	P90	PF16	PF47	G17	BG17

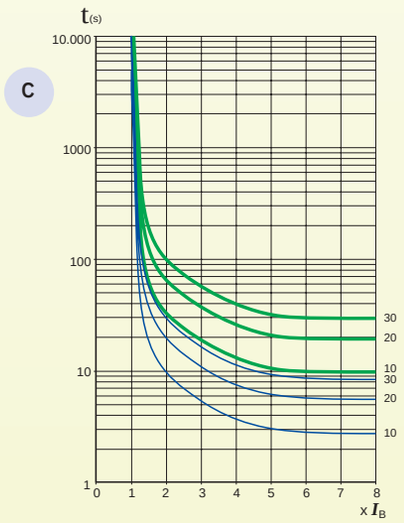
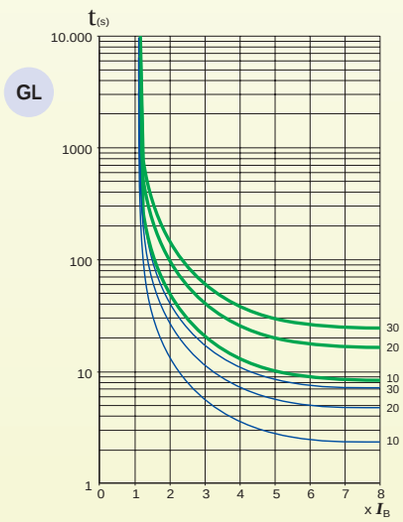
40	30	30	30	25	30	35				30	30	20	20

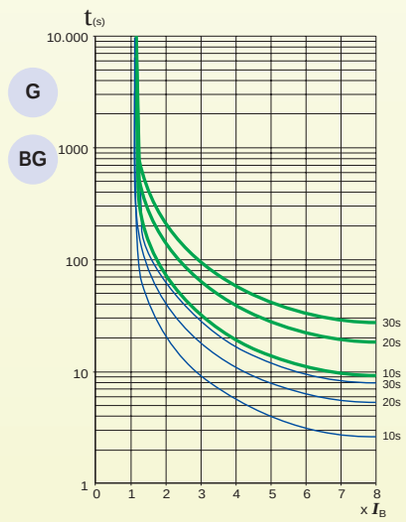
Average trip curves (IEC 947-4-1)

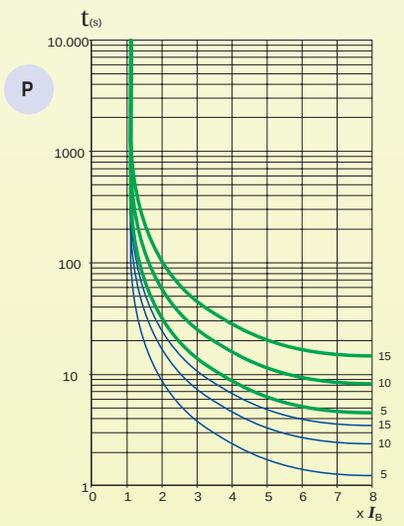
Cold curve: it represents the performance of the relay without any previous current flow, first start.

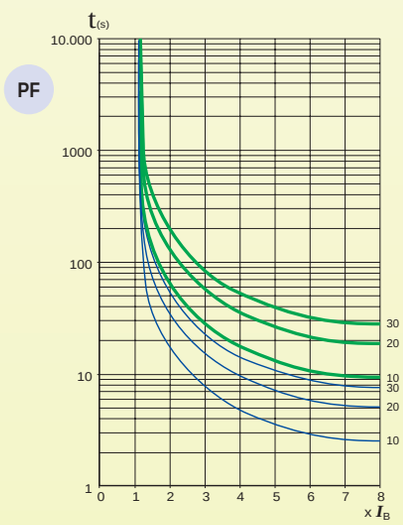
Warm curve: the tripping times decrease as the current flows, and are adapted to the motor heating condition based on the thermal memory, the warm condition (IEC-255) is reached after a current of 0.9 x I_N (motor rated current) flows during 2 hours approximately.

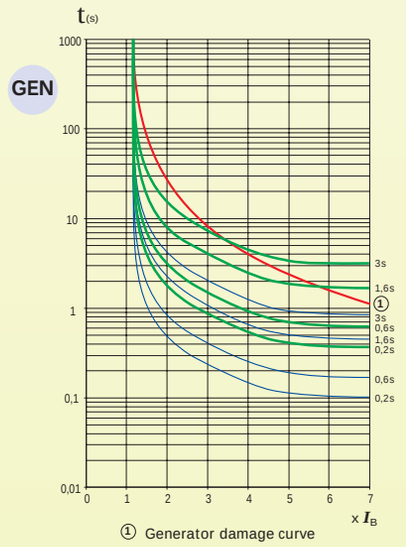












① Generator damage curve

2.4. Underload by cos φ. PF

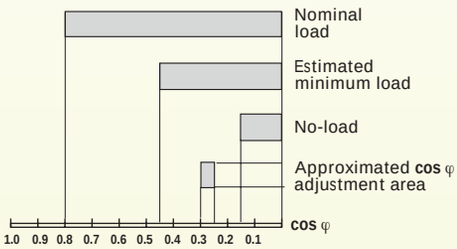
The cos φ underload trip level is set by means of a potentiometer from 0,1 to 0,9.

Select this value taking into consideration the no-load motor cos φ and that corresponding to the estimated minimum operating load. Choose an intermediate value between these two cos φ levels and set it in the relay.

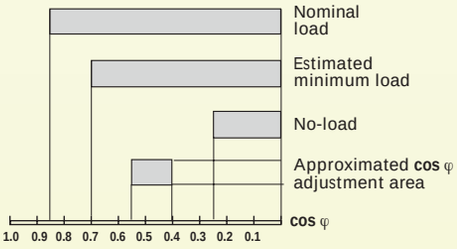
Select the underload trip delay from 5 to 45 seconds and set it with the 3 corresponding dipswitches (trip delay).

For your guidance you can find below two practical examples.

a) A very oversized motor for its application. The cos φ of the motor is 0,15 when working without load.



b) A slightly oversized motor for its application. The cos φ of the motor is 0,25 when working without load.



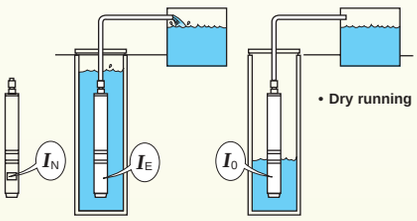
If the above mentioned cos φ values are unknown, the underload trip setting can be made in the following way:

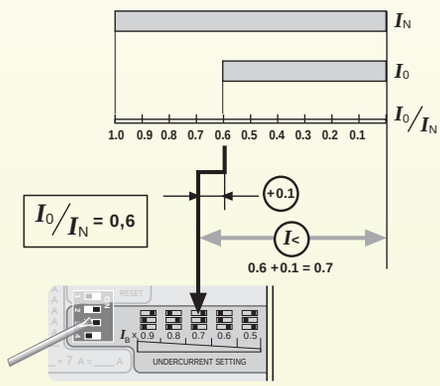
1. Set the underload trip delay to zero by moving the three dipswitches to the left (trip delay).
2. Using the potentiometer (cos φ setting), set the cos φ value to the minimum 0,1.
3. Start up the motor and run it with the minimum estimated load.
4. Slowly turn the cos φ potentiometer clockwise until the relay trips and the cos φ LED lights up.
5. Turn the cos φ potentiometer anticlockwise until the cos φ is set at approximately 30% less than the previous value (point 4).
6. Set the underload trip delay using the 3 corresponding dip switches.

2.5. Undercurrent. P

The undercurrent trip level in P relays is set using three dipswitches. To avoid nuisance trips, set this level to approximately 10% above the no-load motor current.

Example:





2.6. Incorrect phase sequence

Monitoring the current. GL and P

An incorrect phase sequence is detected by current sensing and it is only operative during the motor start-up, for correct detection the starting time must be longer than 0.2 s.

In GL relays the user can activate or desactivate this protection by a dipswitch. Should the right phase sequence be critical, move the dipswitch to the "ON" position. If this protection is not required leave it always in the "OFF" position.

As this function is not compatible with the use of frequency inverters, where it is necessary to protect phase sequence in these installations, move the dipswitch to "OFF" and install an "S" type relay.

Monitoring the voltage. PF

An incorrect phase sequence is detected by voltage monitoring.

In the event that an incorrect phase sequence has been detected, the motor will not start-up since the relay is tripped because it has previously detected the wrong phase sequence.

2.7. Reset

Relays	manual	remote	autom.
C, GL, G, BG, GEN	•	•	
P, PF	man	man	auto

Manual reset

Push the "RESET" button.

After tripping due to phase imbalance, phase loss, undercurrent or incorrect phase sequence, the relay could be reset after 2 seconds have elapsed.

When a trip is caused by an overload, the waiting time could be as much as 8 minutes for C, GL, G and GB relays, 5 minutes in P and PF relays, and 1 minute in GEN relays, depending on the severity of the fault.

Remote reset

After the required waiting time, disconnect the relay's auxiliary power supply and then reconnect it after 3 seconds.

In P and PF relays the reset position dipswitch should be set at "man".

Automatic reset

Only available in P and PF relays.

Choose this mode by moving the dipswitch to the "auto" position.

After any kind of trip, resetting will take place in approximately 15 minutes time, continuously for unlimited starts.

3. Operating test. TEST

To perform the trip test for phase loss, the current which passes through the relay must be higher than 0.7 the set current I_B. Under these conditions, push and hold the TEST button for three seconds, the relay will trip due to phase loss and the corresponding LED will light up.

Motor and generator protection relays. Applications and selection guide

Industries

FANOX protection relays for motors and generators have been installed in the most important areas of industry, including:

- OEM (Original Equipment Manufacturers)
- Chemical and petrochemical
- Quarries, gravel pits and cement factories
- Steelworks, iron and steel industry
- Automotive
- Utilities
- Water treatment and distribution
- Mining
- Food industry
- Marine and shipbuilding
- Sugar industry
- Timber industry
- Elevation industry
- Electric generation and cogeneration
- HVAC (Heat Ventilation Air Condition)

Installations

The following is an informative list of the most important applications using FANOX relays:

- Motor Control Centers (MCC)
- EEx e motors in explosive or hazardous environments
- Submergible pumps, in service stations and water pumping, surface pumps and other types.
- Compressors
- Fans, blowers and ventilators
- Industrial refrigeration and air conditioning
- Centrifuges
- Presses
- Cranes, elevators and escalators
- Lifting machinery in general
- Machine tool
- Conveyor belts
- Mills and mixers
- Generators, alternators and electrical generator sets
